Epididymis

- It is a convoluted tubule that lies above and behind the testis.
- **Functions :** maturation and storage of sperms.
- It has head, body and tail.
- The head is connected with the testis by the efferent ductules.
- The tail is continuous with the vas deferens.
- It is separated from the testis laterally by a space called sinus.
- **Blood supply :** testicular artery and vein.

Vas deferens (ductus deferens)

- It is a continuation of the epididymis.
- It passes in the spermatic cord through the inguinal canal (pathway in the anterior abdominal wall) to the abdomen, then to the pelvis.
- On the base of the urinary bladder, it lies medial to the seminal vesicle. Here, it is dilated to form the ampulla.
- **Function :** transportation of sperms from the epididymis to the ejaculatory duct.
- **Arterial supply :** artery to vas deferens from the inferior vesical artery

Seminal vesicles

- They are 2 in number and lie on the base of the urinary bladder lateral to the ampulla of vas deferens.

- **Function :** secretion of the major part (60%) of the seminal fluid.

- **Arterial supply :** inferior vesical and middle rectal arteries.
