Descent of the Testis

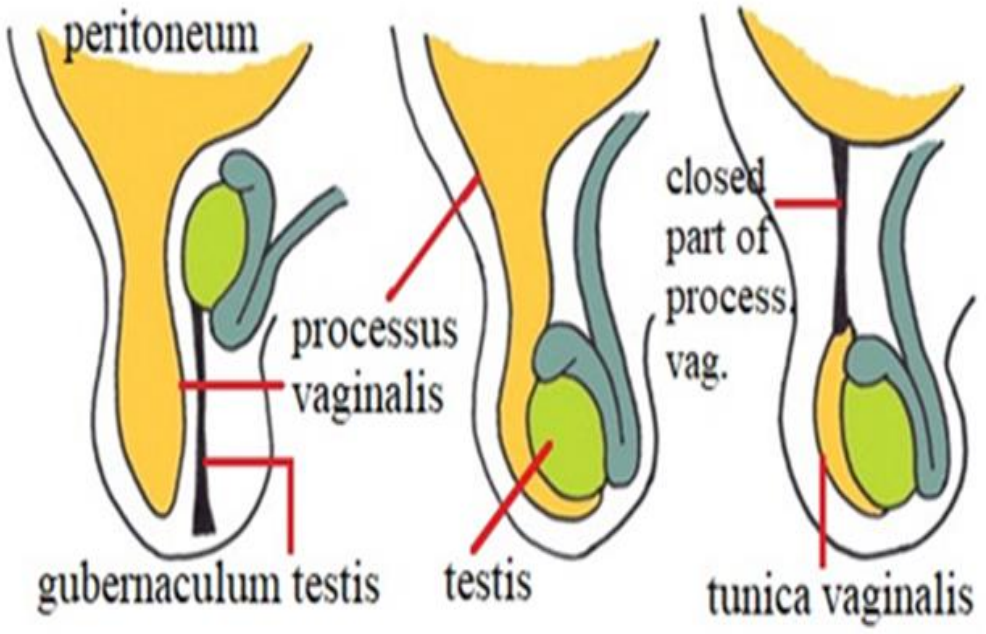

- Gubernaculum testis :

- It is a fibro-elastic band that has 2 ends:

- One end is attached to the lower pole of the testis and the other end is attached to the scrotum.

- Contraction of this band leads to descent of the testis. During its descent, the testis passes through the inguinal canal.

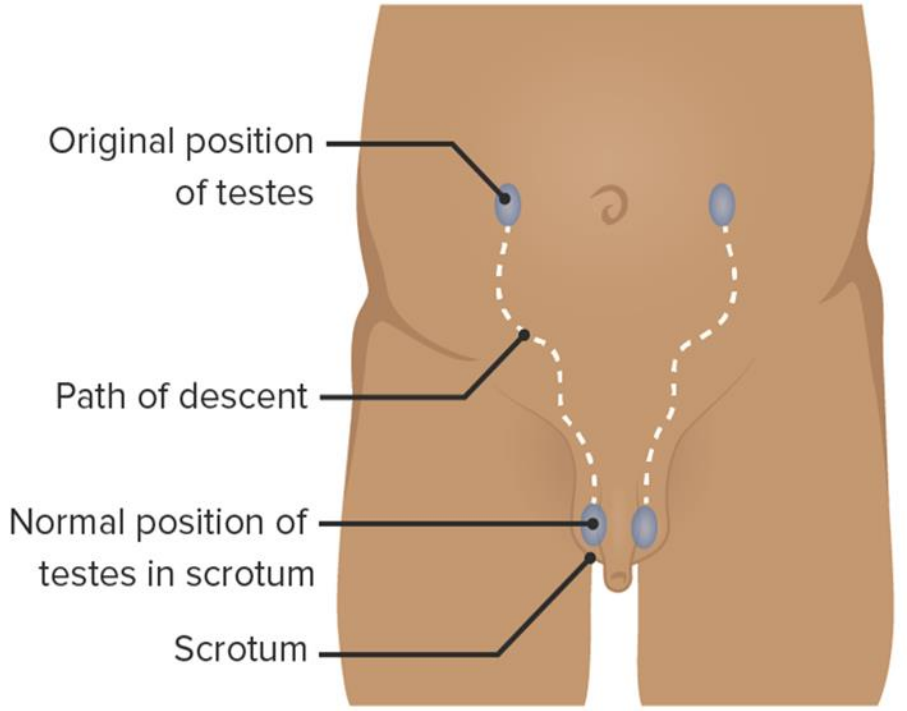

Descent of the testes

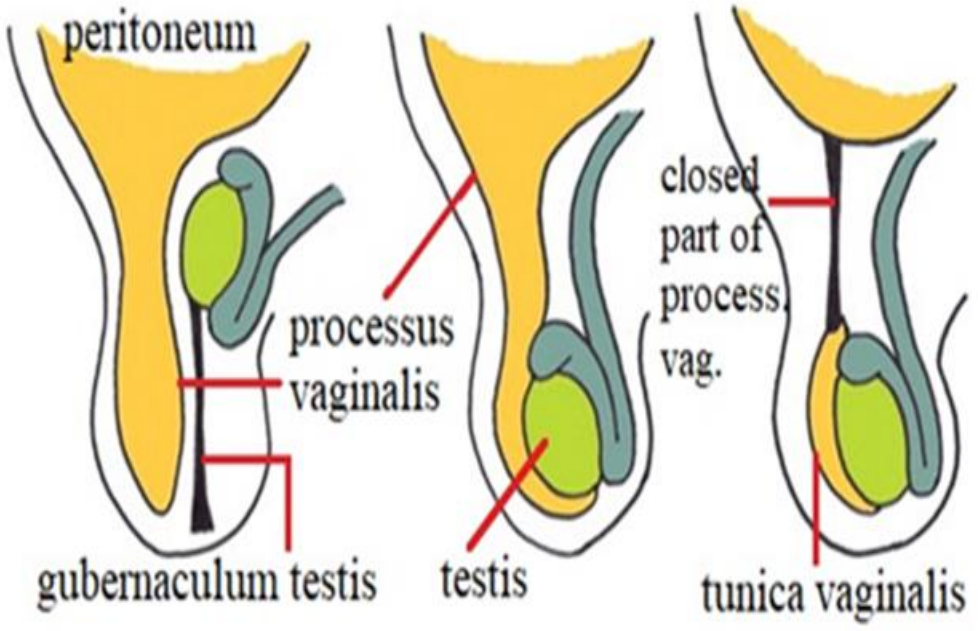

- **Processes vaginalis :**
- A protrusion of the peritoneal cavity that follows the testis through the inguinal canal to the scrotum.

- In the scrotum, the testis invaginates the processes vaginalis, hence the testis is covered by visceral and parietal layers of tunica vaginalis.

- The upper part of the processes vaginalis obliterates forming the vestige of processes

vaginalis and loses connection with the peritoneal cavity.

Factors controlling the descent of the testis

- Hormonal factor: under the effect of androgenic hormone, the testis descends.
- Increase in the intraabdominal pressure.
- Regression (contraction) of the gubernaculum testis.
